Research Question:
How does Rising CO2 Concentration Affect Northern and Southern Hemisphere Temperature Anomalies?

Global Average Temperature Change (°C) = 6.4676 + (0.0141 * CO2_Value) + (-0.0056 * year)

6.4676 is the intercept, for every 1 unit increase in CO2 concentration (ppm), temperature increases by 0.0141 celsius, and for every additional year, temperature decreases by 0.0056 degrees celsius

Conclusion - Rising temperatures are strongly associated with rising CO2 concentrations. Although counterintuitive, year is assigned a negative value due to overlap in explanatory power, as temperature should rise over time
