

Does the relationship between household income and life expectancy differ between men and women?

$$le_i = B_0 + B_1 \text{ Gender}_i + B_2 \log(\text{Income}_i) + B_3 (\text{Gender} \times \log(\text{Income}_i)) + e$$

Regression Results

For every 1% increase in household income, there is an approximate 0.0179 year increase in life expectancy for women, and a 0.0289 year increase in life expectancy for men.

- Baseline life expectancy is lower for men than women but an increase in household income has a much stronger positive impact for men than women.
- Pattern in the residual plot might suggest heteroscedasticity though p-values = 0.000
